

IN THE SPECIFICATION:

At page 1, lines 1-2, the Title has been amended as follows:

A1
--A METHOD TO SYNCHRONIZE DATA
AND A TRANSMITTER AND A RECEIVER REALIZING SAID METHOD--.

At page 1, prior to line 4, please insert new heading and text, as follows:

--PRIORITY CLAIM

A2
In addition to claiming priority under 35 USC §119(a) from EPO Application 96402393.1 filed November 8, 1996, this application also claims the benefit under 35 USC §119(e) of U.S. Provisional Application No. 60/052,126, filed July 10, 1997, and under 35 USC §120, of U.S. Patent Application No. 08/965,136, filed November 6, 1997.---. *cont.*

Also at page 1, prior to line 4, please insert new headings as follows:

--BACKGROUND OF THE INVENTION

A3
1. Technical Field--.

At page 1, the paragraph beginning at line 4 has been rewritten as follows:

A4
--The present invention relates to a method to synchronize data, and a transmitter and a receiver realizing said method.--.

At page 1, line 7, please insert a new heading as follows:

A5
--Discussion of Related Art--.

At page 1, the paragraph beginning at line 7 has been rewritten as follows:

A6
--Such a method to synchronize data is common knowledge. Indeed, e.g., in communication systems where data is sent from a

transmitter to a receiver, for the receiver to be able to interpret the received data, the received data have to be synchronized in the receiver with a reference signal, usually a clock signal of the receiver. Realizing synchronization implies more complexity and therefore there is a need for additional hardware or software in the receiver. The trade-offs are generally between expense and complexity, on the one hand, and error performance on the other hand. However, some kind of receivers, e.g., receivers using asymmetric digital subscriber line technology are required to have both, a low complexity and also a low error performance.--.

At page 1, prior to line 17, please insert a new heading as follows:

--SUMMARY OF INVENTION--.

At page 1, the paragraph beginning at line 17 has been rewritten as follows:

--An object of the present invention is to provide a method to synchronize data and a transmitter and a receiver realizing said method of the above known type but which are suited for use in communication systems where a low complexity and a low error performance are required at the receiving side of the communication system.--.

At page 1, please cancel lines 22-24 and insert new text as follows:

--According to a first aspect of the invention, a method to realize synchronization in a receiver, of data sent from a transmitter to said receiver, with a signal available in said receiver, is characterized in that said method includes the steps of: in said receiver generating trigger signals from said signal

available in said receiver, sending said trigger signals from said receiver to said transmitter, and upon receipt of said trigger signals by said transmitter sending said data from said transmitter to said receiver.

AG
According to a second aspect of the invention, a receiver for receiving data from a transmitter, said data having to be synchronous with a signal available in said receiver, is characterized in that said receiver includes trigger generating means to generate trigger signals from said signal available in said receiver, trigger sending means to send said trigger signals from said receiver to said transmitter, and data receiving means to receive said data sent by said transmitter to said receiver upon receipt of said trigger signals.

According to a third aspect of the invention, a transmitter for transmitting data to a receiver, said data having to be synchronous with a signal available in said receiver, is characterized in that said transmitter includes trigger receiving means to receive trigger signals, generated by said receiver from said signal available in said receiver and sent from said receiver to said transmitter, and data sending means to send data from said transmitter to said receiver upon receipt of said trigger signals.--.

At page 1, the paragraph beginning at line 25 has been rewritten as follows:

A10
--Indeed, due to the trigger signals generated from the signal available in the receiver and sent to the transmitter, the transmitter is able to send the data to the receiver upon receipt of the trigger signals, i.e., at the right time to ensure synchronization between the data received in the receiver and the available signal, e.g., a clock signal in the receiver. In this way, the complexity of the synchronization process is moved from

A10
Cont. the receiver side to the transmitter side of the communication system and each level of synchronization can be realized with the required level of error performance and without making the receiver too complex.--

At page 2, the paragraph beginning at line 3 has been rewritten as follows:

A11 --Another characteristic feature of the present invention is that the data, sent from the transmitter to the receiver, is asynchronous data. Indeed, upon receipt of the trigger signals, the transmitter must be able to send data even if the trigger signals are sent in an asynchronous way. This is for instance the case when the receiver has to receive the data at a time moment at which the data has to just fit at a predefined place in a frame. In this way frame synchronization is achieved.--

At page 2, the paragraph beginning at line 10 has been rewritten as follows:

A12 --Yet another characteristic feature of the present invention is that in the even that no data is available in the transmitter to be sent upon receipt of the trigger signals, the transmitter is able to generate idle data and to send this idle data to the receiver. In this way, e.g., the frame synchronization process is not disturbed.--

At page 2, the paragraph beginning at line 16 has been rewritten as follows:

A13 --An important application of the present invention is that the receiver is included in an asymmetric digital subscriber line (ADSL) modem. In such a receiver, the received data is framed into an asymmetric digital subscriber line frame and sent over a twisted pair. However in known ADSL modems using the known

A13
Cont.

synchronization methods, when the modem receives data at a higher frequency than the frequency at which the data is sent, the data has to be buffered before being framed. As already mentioned above, it is important to keep the complexity of a receiver in such a modem low. By using the method of the invention, the asymmetric digital subscriber line modem gets rid of, i.e., avoids, the buffering aspect. In fact, the buffering is again moved from the receiver to the transmitter which now must be able to buffer the data until it receives a trigger signal of the receiver to have the permission to send the data to the receiver. Therefore, this way of synchronizing is especially suited for systems wherein there is anyway buffering foreseen at the transmitting side, e.g., for Asynchronous Transmission Mode (ATM) systems. --

A14

At page 3, prior to line 1, please insert a new heading as follows:

--BRIEF DESCRIPTION OF THE DRAWING--.

A15

At page 3, the paragraph beginning at line 1 has been rewritten as follows:

--The above-mentioned and other objects and features of the invention will become more apparent and the invention itself will be best understood by referring to the following description of an embodiment taken in conjunction with the accompanying sole figure which is a schematic block diagram of a synchronization system including a transmitter and a receiver realizing the method of the invention.--.

A16

At page 3, prior to line 6, please insert a new heading as follows:

--DETAILED DESCRIPTION OF PREFERRED EMBODIMENT--.

[At page 3, the paragraph beginning at line 6 has been rewritten as follows:

A16 1/2
--Referring to the figure, the working of the synchronization system will be described. First, the working of the synchronization system will be explained by means of a functional description of the blocks shown in the Figure. Based on this description, implementation of the functional blocks will be obvious to any person skilled in the art and will therefore not be described in detail. In addition, the principle working of the synchronization system will be described in further detail.--

[At page 3, the paragraph beginning at line 13 has been rewritten as follows:

A17
--The synchronization system includes a transmitter TX and an asymmetric digital subscriber line modem (ADSL modem) ADSL.--

[At page 3, the paragraph beginning at line 20 has been rewritten as follows:

A18
--The buffer BUF is included to buffer the data DAT presented to the transmitter TX. This data DAT can be digital data of any kind, however, for this embodiment the data DAT is asynchronous data, i.e., data organized following the asynchronous transfer mode (ATM) technique. As mentioned, the buffer BUF buffers the data DAT presented to the transmitter TX. However, it has to be understood that the buffer BUF will only do this when it is necessary, i.e., when the transmitter receives more data DAT than it is allowed to send.--

[At page 3, the paragraph beginning at line 27 has been rewritten as follows:

A19
--The idle data generating means ID-GEN is included to generate idle data. It has to be remarked that this is provided to enable the use of one of the typical ATM functionalities. Idle data is sent whenever there is no information available at the side of the sender at the moment of transmission. This allows a fully asynchronous operation of both sender and receiver.--

[
At page 4, the paragraph beginning at line 5 has been rewritten as follows:

A20
--The trigger receiving means T-RX is included to receive trigger signals T coming from the ADSL modem. Upon receipt of such a trigger signal, the data sending means DAT-SEND is in turn triggered by the trigger receiving means T-RX and is allowed to send data.--

[
At page 4, the paragraph beginning at line 9 has been rewritten as follows:

A21
--The ADSL modem includes besides a receiver RX also the characteristic functional blocks of an ADSL modem. Since the description of the ADSL technology goes beyond the scope of this invention, these functional blocks are not shown in the figure. However, it is worth mentioning here that one of the functional clocks of such an ADSL modem is a framer which organizes overhead information and user information, i.e., the incoming data DAT into ADSL frames, i.e., uniformly sized groups of bits used to organize the ADSL data stream.--

[
At page 4, the paragraph beginning at line 20 has been rewritten as follows:

A22
--The trigger generating means T-GEN is included to generate trigger signals T from an available signal SIG in the receiver RX. This available signal SIG is generated in accordance with the time moments whenever data DAT is needed to fit into an available ADSL frame in a predetermined place. This signal SIG is not necessarily a clock signal. Indeed, looking to the form of an ADSL frame, the whole frame need not be filled with data DAT, so as a consequence, the signal SIG is not a signal with a constant frequency.--

[
At page 4, the paragraph beginning at line 27 has been rewritten as follows:

A23
--It has to be remarked here that the trigger signals T are allowed to be of any kind, e.g., one single bit pulse or a predefined codeword as long as the trigger generating means T-GEN of the receiver RX and the trigger receiving means T-RX of the transmitter can recognize the trigger signals T.--

[
At page 5, the paragraph beginning at line 4 has been rewritten as follows:

A24
--The transmission medium for sending the trigger signals is in the figure depicted as a separate line to simplify the description of the working of the system. However, these signals can (and usually are) transmitted over the same transmission medium, i.e., a single twisted wire pair, as the data.--

[
At page 5, the paragraph beginning at line 8 has been rewritten as follows:

A25
--The principle working of the synchronization system will be described in the following paragraph.--

At page 5, the paragraph beginning at line 10 has been rewritten as follows:

A26
--Whenever data DAT is needed to fit in an available ADSL frame in a predetermined place, a trigger signal T is generated from the available signal SIG and transmitted to the transmitter TX. Upon receipt of a trigger signal T the trigger receiving means T-RX gives a signal to the data sending means DAT-SEND, e.g., by means of a control signal, and DAT-SEND in turn makes a signal request for data DAT to the buffer BUF. When there is data DAT available in the buffer BUF, the data DAT is provided to the data sending means DAT-SEND. However, when no data DAT is available in the buffer, the synchronization process may not be disturbed and the data sending means DAT-SEND requests idle data to the idle data generating means ID-GEN. The data, either user data or idle data, is sent to the receiver RX and arrives there at the right moment to fit immediately into the ADSL frame in the predetermined place whereby synchronization is established between the data DAT and the available signal SIG.--.

At page 5, the paragraph beginning at line 23 has been rewritten as follows:

A27
--It has to be remarked that upon receipt of a trigger signal T, the transmitter TX has to send data DAT to the receiver RX. Sending data can be done immediately after receiving of the trigger signal T, however the invention is not restricted to such kind of synchronization systems but is also applicable for synchronization systems where the data DAT is only sent after a predetermined period. Indeed, in this particular embodiment, the total period between the moment of generating a particular trigger and the moment of data DAT arriving at the receiver RX to accordingly fit into a predefined ADSL frame must be taken into account at initialization time. It can be necessary to have a

A27
cont. predetermined waiting period somewhere in the loop in order to be able to realize the synchronization. Since the complexity is moved from the receiver RX to the transmitter TX, this waiting period will also be realized by the transmitter TX.--

IN THE ABSTRACT:

At page 9, please cancel lines 1-3 and substitute a new heading as follows:

--ABSTRACT OF THE DISCLOSURE--.

A28
At page 9, the paragraphs beginning at line 5 have been rewritten as follows:

A method to realize synchronization in a receiver (RX), of data (DAT) sent from a transmitter (TX) to the receiver (RX), with a signal (SIG) available in the receiver (RX). The method includes the following steps:

- A29
- in the receiver (RX) generating trigger signals (T) from the signal (SIG);
 - sending the trigger signals (T) from the receiver (RX) to the transmitter (TX); and
 - upon receipt of the trigger signals (T) by the transmitter (TX) sending the data (DAT) from the transmitter (TX) to the receiver (RX).--.
